SECTION 02

Executive Summary

A fixed-supply utility token designed around transparent constraints

OvaSHA is a community-oriented utility protocol deployed on BNB Smart Chain. Its core token, OVA, has a fixed maximum supply of 45,000,000 tokens. The contract does not expose a minting function capable of increasing that cap after genesis. The architecture combines predefined allocation pools, a low fixed transfer tax, staking incentives, scheduled burns, liquidity controls, a public timelock and multisig-based ownership.

The protocol is deliberately conservative. Rather than relying on high emissions or frequently adjustable fees, OvaSHA uses a small set of visible rules that can be inspected on-chain. The intention is not to eliminate all risk - no smart contract or market can do that - but to reduce avoidable ambiguity and privileged discretion.

OvaSHA separates what exists today from what may be developed later. The deployed token contract, verification status, fixed supply, allocation logic, staking parameters, scheduled burns and administrative controls are current protocol facts. Broader ecosystem utilities, formal DAO governance, third-party audits, bug bounty programs and exchange expansion remain milestones subject to execution, legal review and community readiness.

SECTION 03

Founding Thesis

Trust should be supported by visible rules, not promotional language

Digital asset markets have repeatedly demonstrated the cost of hidden mint authority, instantly changeable fees, unrestricted treasury access and unclear allocations. OvaSHA was created from a different premise: a protocol earns credibility when its rules are observable, its powers are bounded and its future claims are clearly distinguished from deployed functionality.

The project therefore favors predictable constraints over aggressive flexibility. The maximum supply is established at genesis. Key reserves are separately accounted for. Administrative actions are delayed through a timelock. Ownership is designed around a 2-of-3 multisig configuration rather than a single externally owned account. Liquidity release requires both the passage of the lock period and a prior proposal.

These controls do not make the system fully decentralized. At version 1.0, operational authority remains with the multisig. OvaSHA treats this as an explicit transitional model: secure operational stewardship first, progressively wider governance only after the ecosystem has sufficient infrastructure, participation and risk controls.

“Trust is earned through transparent code - not promises.”

The founder’s role is therefore framed as accountable stewardship. The protocol is intended to be judged by its deployed code, public transactions, documented allocations and delivery against stated milestones.

SECTION 04

Design Principles

Five principles guide protocol decisions

01

Fixed before flexible

Core supply and primary allocation rules are predetermined. Future utility should be added around the token rather than by changing its foundational scarcity.

02

Delay before execution

Sensitive administrative operations use a public waiting period, giving observers time to review proposals before execution.

03

Separation of purpose

Founder, marketing, emergency, liquidity, strategic exchange, presale, airdrop, burn and mining/staking allocations are separately defined.

04

Measured incentives

Staking begins at a modest 2% annual rate to reduce emission pressure and support sustainability rather than short-term yield competition.

05

Progressive decentralization

DAO governance is a roadmap objective, not a current claim. Governance expansion should follow product maturity and risk readiness.

SECTION 05

Protocol Overview

How the principal components fit together

OvaSHA is implemented as a BEP-20 compatible token contract using Solidity 0.8.20. The contract contains the token ledger, allocation accounting, staking logic, taxation, scheduled burn mechanisms, liquidity deployment and release controls, emergency restrictions and timelocked administrative actions.

Operational sequence

At deployment, the full fixed supply is assigned according to contract-defined pools. DEX liquidity can be deployed only once and is paired with native BNB through the configured PancakeSwap V2-compatible router and factory. LP tokens remain held by the token contract until the lock duration expires and the timelocked release process has been completed.

Transfers not excluded from taxation incur the fixed 0.20% tax. Staking positions lock principal inside the contract, while the mining/staking reward reserve funds rewards subject to availability and contract rules.

SECTION 06

Network and Contract

Deployment facts and verification

Network	BNB Smart Chain Mainnet
Chain ID	56
Standard	BEP-20 / ERC-20 compatible interface
Compiler	Solidity 0.8.20
Token name	OvaSHA
Symbol	OVA
Decimals	18
Contract address	0xd0E2B14083D44C23B36ee7009539eEEF56b712B2
Deployment transaction	0xe2c7d3006b7c8072a1a5217fcbce6f02af13663d3d3800ddb53163cd34d37c15
Source verification	BscScan Exact Match

Why exact-match verification matters

Exact-match verification allows the public source code and compiler settings displayed by BscScan to reproduce the deployed bytecode. It improves inspectability and reduces uncertainty about whether the published source corresponds to the live contract. Verification is not the same as an independent security audit and should not be presented as one.

Immutability boundaries

The contract itself is not described as upgradeable. Future applications can integrate OVA or use separate contracts, but those additions should be independently documented and assessed. The token's fixed supply and existing deployed logic remain governed by the code at the verified address.

SECTION 07

Tokenomics

A 45 million fixed supply with purpose-specific reserves

All percentages sum to 100% of the genesis supply. The mining/staking reward pool is the calculated remainder after the named allocations and equals 2,700,000 OVA, or 6% of total supply.

Economic intent

The largest allocation is reserved for DEX liquidity to support an accessible market. A separate CEX and strategic reserve is intended for future exchange liquidity, integrations and ecosystem opportunities. The presale pool is capped at 5%. Scheduled burn pools account for a combined 5% of genesis supply and cannot be treated as circulating utility reserves.

SECTION 08

Supply Allocation

Quantities, percentages and functional constraints

Allocation	OVA	Share	Purpose
DEX Liquidity	21,150,000	47%	Initial decentralized exchange liquidity
CEX & Strategic Reserve	11,250,000	25%	Exchange liquidity and strategic ecosystem use
Presale	2,250,000	5%	Capped token sale allocation
Mining / Staking Rewards	2,700,000	6%	Funding of protocol staking rewards
Emergency	2,250,000	5%	Restricted contingency reserve
Marketing	1,350,000	3%	Communications, growth and ecosystem operations
Founder	900,000	2%	Founder allocation, subject to contract transfer constraints
Airdrop	900,000	2%	Community distribution
Scheduled Burn 2028	1,125,000	2.5%	Time-gated destruction
Scheduled Burn 2030	1,125,000	2.5%	Time-gated destruction

No post-genesis minting

The maximum supply is fixed at deployment. The absence of an externally callable mint function means the project cannot increase supply through routine administration. Supply may decline through scheduled burns, transaction-tax burns and voluntary burn mechanisms.

Circulating supply is not total supply

A fixed total supply does not imply that every token is immediately circulating. Contract-held reserves, locked liquidity positions, scheduled burn pools and undistributed allocations should be reported separately when public circulating-supply disclosures are prepared.

SECTION 09

Transfer Tax

A fixed 20 basis-point tax with predefined routing

The contract defines a total transfer tax of 20 basis points, equal to 0.20%. The rate is intentionally small relative to many tax-based tokens and is represented as a constant rather than a freely adjustable owner parameter.

Component	Share of tax	Effective transfer rate
Burn	25%	0.05%
Buyback address	25%	0.05%
Marketing address	50%	0.10%
Total	100%	0.20%

Illustrative transfer

For a taxable transfer of 100,000 OVA, the total tax is 200 OVA. Based on the defined split, 50 OVA is burned, 50 OVA is routed to the buyback address and 100 OVA is routed to the marketing address. The recipient receives 99,800 OVA.

Exclusions and governance

Tax exclusions are distinct from wallet-limit exclusions. The contract includes controls intended to prevent a predicted or created DEX pair from retaining an inappropriate tax exemption. The tax-exclusion registry can be permanently locked, reducing the ability to add new privileged exemptions after the project reaches the relevant operational stage.

SECTION 10

Burn Architecture

Three pathways for reducing supply

1. Transaction-tax burn

One quarter of the 0.20% transfer tax is routed to the canonical dead address, producing an effective burn of 0.05% on taxable transfers. The absolute amount depends on transaction activity and cannot be forecast with certainty.

2. Scheduled burns

Two dedicated pools of 1,125,000 OVA each are reserved for time-gated burns. The first is scheduled for 10 January 2028 at 00:00 UTC; the second for 1 January 2030 at 00:00 UTC. Together they represent 2,250,000 OVA, or 5% of genesis supply.

3. Voluntary burn

The protocol also supports voluntary destruction of tokens under the relevant contract rules. Voluntary burns must not be presented as guaranteed future supply reduction because they depend on actual holder or treasury decisions.

Interpretation

Burns reduce token quantity but do not, by themselves, create demand or guarantee price appreciation. OvaSHA treats burn mechanics as transparent supply policy rather than a promise of investment performance.

SECTION 11

Staking Model

Low-emission incentives with protected principal accounting

OVA staking is embedded in the deployed contract. The model uses a 2% annual percentage rate, a 30-day staking duration and a 7-day minimum stake time. Rewards are funded from the finite mining/staking reserve rather than newly minted supply.

Parameter	Value
Annual staking rate	2% APR
Standard duration	30 days
Minimum stake time	7 days
Reward source	2,700,000 OVA mining/staking reserve
Mint-based inflation	None

Reward example

A 100,000 OVA position held for 30 days at a 2% annual rate generates approximately 164.38 OVA before considering integer rounding and exact contract calculation conventions: $100,000 \times 2\% \times 30 / 365$.

Principal protection

The contract tracks staked principal as reserved balance. Recovery and treasury operations are restricted from consuming protected user principal or the dedicated reward reserve. This reduces accounting ambiguity, although users remain exposed to smart-contract and market risks.

Finite reward policy

Because rewards are paid from a fixed reserve, staking is not perpetual by assumption. Reward availability depends on remaining pool capacity and protocol usage. Future parameter or product changes should be disclosed separately and must not be implied by this v1.0 model.

SECTION 12

Liquidity Design

One-time deployment, slippage limits and time-locked LP release

The contract integrates with a PancakeSwap V2-compatible router and factory on BNB Smart Chain. The DEX liquidity allocation is 21,150,000 OVA, equal to 47% of total supply. Initial liquidity deployment can occur only once.

Deployment safeguards

The deployment function validates the configured router and factory, requires native BNB, enforces non-zero minimum amounts and applies a hard-coded maximum liquidity slippage policy of 3%. The function follows checks-effects-interactions ordering and is protected by a reentrancy guard.

LP custody and release

LP tokens are initially held by the OvaSHA token contract. The lock duration is 365 days from liquidity deployment. Expiry alone is insufficient: LP release also requires a prior timelocked proposal and successful execution after the 48-hour delay.

1	Provide BNB and minimum amounts	Owner initiates one-time liquidity deployment.
2	Create or resolve pair	The contract verifies the pair through the configured factory.
3	Receive LP tokens	LP position is held by the token contract.
4	Observe 365-day lock	Release is unavailable before lock expiry.
5	Propose release	A public timelock proposal is created.
6	Execute after 48 hours	Release occurs only after both conditions are met.

SECTION 13

Treasury and Reserves

Purpose-built pools with restricted use

OvaSHA's treasury design separates operational resources by purpose. This does not eliminate treasury risk, but it makes the intended role and maximum genesis quantity of each reserve easier to inspect.

Reserve	Amount	Governance intent
CEX & Strategic	11,250,000 OVA	Exchange liquidity, integrations and strategic ecosystem activity
Marketing	1,350,000 OVA	Communication, growth, partnerships and project operations
Emergency	2,250,000 OVA	Contingency response under restricted conditions
Founder	900,000 OVA	Founder allocation with contract-level transfer constraints
Airdrop	900,000 OVA	Community distribution
Presale	2,250,000 OVA	Capped sale allocation; operational execution must be separately disclosed

Emergency reserve

Emergency access is not intended as a discretionary revenue source. The contract uses time-delayed actions and reserve checks. Public communications should explain the reason, destination and transaction hash for any emergency operation.

Founder allocation

The founder pool is 2% of total supply. The contract is designed so that the founder allocation is transferred to a contract-based vesting destination rather than an arbitrary externally owned wallet. Any separate vesting contract should be independently verified and documented before distribution.

SECTION 14

Governance and Multisig

Secure operational control before broader decentralization

At version 1.0, OvaSHA is not a DAO. Administrative ownership is required to be a Safe-compatible 2-of-3 multisig. This structure reduces single-key risk because routine ownership actions require coordination across multiple signers.

What multisig improves

A 2-of-3 threshold can prevent one compromised or unavailable key from unilaterally controlling the protocol. It also supports operational continuity if one signer is lost, provided the remaining signers act safely.

What multisig does not solve

Multisig does not create full decentralization. Two signers can still coordinate, make poor decisions or become compromised. Signer identity, device security, backup procedures, transaction simulation and public disclosure remain important operational controls.

Ownership transfer constraints

The contract includes validation intended to restrict ownership transfer to another compatible 2-of-3 multisig configuration. This reduces the risk of silently replacing multisig governance with a single wallet.

Future DAO path

DAO governance is a roadmap objective. A credible transition would require a defined proposal process, quorum, voting power policy, delegation rules, emergency boundaries and a clear separation between governance rights and immutable token rules. No DAO functionality should be marketed as active until deployed and publicly tested.

SECTION 15

Timelock System

Public delay as a governance safety layer

Sensitive administrative operations use a 48-hour timelock. The owner first proposes an action, the proposal is recorded, and execution becomes available only after the delay. This makes administrative intent visible before the state change occurs.

Covered action classes

The timelock framework is used for actions such as changing exclusions, adjusting the maximum-wallet setting within permitted bounds, locking the exclusion registry, proposing LP release and executing restricted marketing or emergency operations.

Proposal integrity

The contract records proposal parameters and includes protections against executing nonexistent, already executed or cancelled proposals. For contract targets, code-hash checks are used to detect target-code changes between proposal and execution.

Limitations

A timelock is an observation window, not a veto by itself. Users must monitor proposals, and the ecosystem needs clear alerting channels. The 48-hour delay may also slow legitimate emergency response. OvaSHA chooses this trade-off to prioritize reviewability for privileged actions.

SECTION 16

Security Controls

Defense in depth, with explicit limits

✓	Reentrancy guard Protects external-call flows such as liquidity operations and withdrawals from nested execution.
✓	Checks-effects-interactions State changes are ordered before external interactions where applicable.
✓	Custom errors Explicit revert conditions improve gas efficiency and make failure classes easier to identify.
✓	Allocation invariants Internal checks protect the consistency of reserved pools and contract-held balances.
✓	Protected principal Staked user principal is reserved from recovery or treasury consumption.
✓	Protected reward pool Mining/staking rewards are separately accounted for and cannot be casually recovered.
✓	Router/factory validation DEX configuration is checked against the intended liquidity architecture.
✓	Maximum slippage policy Initial liquidity parameters cannot exceed the hard-coded 3% tolerance.
✓	No arbitrary mint Supply cannot be expanded after genesis through an owner mint function.
✓	Pausable controls Emergency pause functionality exists for defined protocol operations, subject to governance constraints.

Important: These controls reduce specific risk categories but do not prove the absence of vulnerabilities. At publication, OvaSHA should not claim formal verification, a completed independent audit or an active bug bounty unless those items are separately completed and publicly evidenced.

SECTION 17

Administrative Boundaries

What privileged actors can and cannot do

Area	Boundary
Supply	No post-genesis minting above the fixed 45,000,000 OVA cap.
Tax	Total tax is defined as a constant at 0.20%; it is not an unrestricted owner-set variable.
Wallet limit	Adjustable only inside contract-defined boundaries; initial configuration is disclosed on-chain.
Tax exemptions	Registry controls exist and can be permanently locked.
Liquidity	Initial deployment is one-time; LP release requires both lock expiry and timelock.
Treasury	Withdrawals are limited by pool purpose, balance invariants and timelocked execution.
Staking principal	Reserved user principal cannot be treated as recoverable treasury balance.
Ownership	Transfer is restricted toward a compatible 2-of-3 multisig configuration.

Operational transparency standard

Every privileged transaction should be accompanied by a plain-language explanation, expected impact, destination address and transaction hash. Where a timelock proposal exists, communication should occur at proposal time rather than only after execution.

SECTION 18

Risk Framework

A credible protocol discloses uncertainty

Smart-contract risk. Undiscovered logic errors, integration assumptions or edge cases may cause loss, lockup or unexpected behavior.

Market risk. OVA price, liquidity and trading volume may be highly volatile. Burns and fixed supply do not guarantee value.

Liquidity risk. Insufficient liquidity can produce price impact, slippage and difficulty entering or exiting positions.

Administrative risk. Multisig signers may be compromised, unavailable or act contrary to stakeholder expectations.

Oracle and integration risk. Future applications, exchanges, bridges or third-party contracts may introduce vulnerabilities outside the token contract.

Regulatory risk. Token issuance, presale, marketing, staking and exchange access may be subject to changing laws across jurisdictions.

Operational risk. Website, domains, social accounts, deployment keys and communication channels can be attacked or mismanaged.

Concentration risk. Large genesis reserves may influence supply distribution and market dynamics before wider distribution.

Roadmap risk. Planned products, DAO governance, audits, listings and partnerships may be delayed, changed or not completed.

Risk management priorities

Near-term priorities include independent audit procurement, public multisig procedures, signer hardware security, proposal monitoring, reserve reporting, a responsible disclosure channel and a bug bounty after sufficient scope definition. None of these controls should be represented as complete until publicly verifiable.

SECTION 19

Roadmap

Milestone-based development rather than date-only promises

COMPLETED / CURRENT	FOUNDATION Mainnet deployment, exact-match verification, official website, token documentation and operational setup.
NEAR TERM	LAUNCH READINESS BscScan profile, whitepaper publication, community channels, liquidity and presale execution subject to legal and operational review.
PLANNED	SECURITY MATURITY Independent audit, remediation disclosure, bug bounty, monitoring dashboards and treasury reporting.
PLANNED	UTILITY EXPANSION Staking interface, analytics, community programs and integrations built around the verified token.
PLANNED	MARKET ACCESS DEX growth, selected exchange relationships and strategic liquidity management.
LONG TERM	GOVERNANCE EVOLUTION Governance research, proposal standards, community voting design and gradual transfer of appropriate powers.

Roadmap milestones are strategic intentions, not guaranteed deadlines. Each milestone should be updated through official channels with evidence of completion.

SECTION 20

Transparency Commitments

Standards for ongoing public accountability

Verified source. Maintain direct links to the verified BscScan contract and publish the canonical contract address consistently.

Reserve reporting. Report material movements from presale, strategic, marketing, emergency and founder allocations.

Timelock notices. Publish privileged proposals when created, including rationale and expected execution time.

Security disclosure. Publish audit scope, final reports, remediation status and known limitations without selective omission.

Clear product status. Label features as live, beta, planned or research. Do not present roadmap functionality as deployed.

Incident communication. Provide timely, factual updates during security, liquidity or operational incidents.

Version discipline. Update this whitepaper when material protocol facts change; retain a public version history.

Official information hierarchy

The verified smart contract is authoritative for on-chain behavior. BscScan and transaction records are authoritative for deployed state and actions. The official website and whitepaper provide interpretation and context but cannot override contract behavior.

Community responsibility

Users should independently verify addresses, use official links, inspect allowances, understand slippage and avoid relying on unsolicited messages. OvaSHA representatives should never request private keys or seed phrases.

SECTION 21

Technical Reference

Core constants and deployed identifiers

Identifier	Value
TOTAL_SUPPLY_CAP	45,000,000 OVA
DEX_LIQUIDITY_POOL	21,150,000 OVA (47%)
CEX_STRATEGIC_RESERVE	11,250,000 OVA (25%)
PRESALE_POOL	2,250,000 OVA (5%)
MINING / STAKING RESERVE	2,700,000 OVA (6%)
FOUNDER_POOL	900,000 OVA (2%)
AIRDROP_POOL	900,000 OVA (2%)
MARKETING_POOL	1,350,000 OVA (3%)
EMERGENCY_POOL	2,250,000 OVA (5%)
BURN_POOL_2028	1,125,000 OVA (2.5%)
BURN_POOL_2030	1,125,000 OVA (2.5%)
TOTAL_TAX_BPS	20 / 10,000 = 0.20%
STAKING_APR	2%
STAKING_DURATION	30 days
MINIMUM_STAKE_TIME	7 days
TIMELOCK_DELAY	48 hours
LP_LOCK_DURATION	365 days
MAX_LIQUIDITY_SLIPPAGE	3%

SECTION 22

Legal and Regulatory Notice

Information only - no promise of return

This whitepaper is provided solely for general informational purposes. It is not a prospectus, offer document, solicitation, recommendation, investment contract, financial promotion or invitation to buy or sell any security, commodity, derivative or financial instrument.

OVA may have no value, may lose all value and may be subject to extreme volatility. No statement in this document guarantees liquidity, exchange listing, adoption, utility, governance participation, income, yield, profit, price appreciation or any other outcome.

Regulatory treatment of digital assets varies by jurisdiction and may change. Prospective users are responsible for obtaining independent legal, tax, accounting and financial advice and for determining whether acquisition, holding, transfer, staking or use of OVA is lawful in their jurisdiction.

Smart contracts and blockchain networks involve technical risk. Verification of source code does not constitute an audit or warranty. Any future audit represents an assessment within a defined scope and time and cannot guarantee that all vulnerabilities have been identified.

Roadmap statements are forward-looking intentions based on current expectations. They may be modified, delayed or discontinued due to technical, commercial, security, legal, regulatory or operational considerations.

Nothing in this document creates a fiduciary relationship. Users retain full responsibility for wallet security, transaction review, address verification, approvals, private keys and compliance obligations.

No reliance

Readers should rely on the verified contract for on-chain mechanics and should independently evaluate all material facts before interacting with OVA.

SECTION 23

Conclusion

A protocol designed to be inspected

OvaSHA begins with a simple premise: sustainable credibility comes from visible constraints, measured incentives and accountable execution. The token's 45 million fixed supply, predefined allocations, modest transfer tax, finite staking reserve, scheduled burns, timelocked administration, one-year LP lock and 2-of-3 multisig ownership form the technical foundation of version 1.0.

The project's next challenge is not to add complexity for its own sake. It is to execute responsibly: establish liquidity, communicate reserve movements, build accessible interfaces, obtain independent security review, expand utility and design governance only when the ecosystem is ready.

OvaSHA does not claim that code removes every risk. It commits to making its rules observable, its limitations explicit and its progress measurable.
